# ION ASSISTED DEPOSITION OF ZnS AND MgF<sub>2</sub> FILM

/815\*

Gu Pei Fu, Chen Yuming, Hu Xuequn and Tang Jinfa<sup>1</sup>

## ABSTRACT

ZnS and MnF<sub>2</sub> films have been prepared by Ar ion assisted deposition. The packing density of MgF<sub>2</sub> has been increased from 0.8 to 0.9-0.95 without ion bombardment as determined by the wavelength shift measurement after moisture absorption by filter. It is shown that high energy bombardment (>1 keV) increases the absorption and scattering loss, while the low energy bombardment is shown to increase significantly the abrasion resistance and adherence of film without affecting the optical properties. Therefore, it will play a very important role in preparing durable coatings for temperature sensitive substrate.

Key Words: Ion assisted deposition, filter.

## I. INTRODUCTION

Deposition of molecules on the surface of substrate or limited migration of atoms is one of the causes of film column structural growth. In 1980s, a proposal was made to increase the migratory ratio of depository ions and to improve the microstructure of the film by supplying certain amount of activation energy to evaporating molecules or atoms with ion bombardment technique. Studies (1-8) on oxide film ion assisted deposition revealed some interesting results. However, hardly any studies on ZnS and MgF<sub>2</sub> have been done except those by Herrmann and Kennemore et al. Herrmann, et al obtained a MgF<sub>2</sub> film by bombarding the cold substrate with 50  $\mu$ A/cm<sup>2</sup>, 700 ev Ar ion which resulted in an

<sup>1</sup> Dept. of Optical Engineering, Zhejiang Univ., Hang Zhou

increased adherence that is equivalent to the one obtained through depositing the hot substrate at 250°C. Kennemore, et al found that  $MgF_2$  bombarded with low energy ion beams ( $<250$  eV,  $5-70 \mu A/cm^2$ ) at room temperature had increased adherence and abrasion resistance, and had higher absorption in short waves ( $\lambda < 275nm$ ). No through studies have been done on the optical stability of  $ZnS$  and  $MgF_2$  film formed by ion assisted deposition. In order to further study the optical and mechanical properties of these films, we made  $ZnS$  and  $MgF_2$  films by using ion assisted deposition. With high energy bombardment, the packing density of  $MgF_2$  film can be reached as high as 0.95, but this is accompanied by higher absorption and abrasion. Bombarding with low energy ions, the adherence of film increases without losing desired optical properties. This practically paves the way for making durable film with room temperature substrate.

## II. THE DESIGN OF THE EXPERIMENT

Three different kinds of ion source were used in the experiment. The first one is high energy (1-2 keV) ion emitting source made by Perkin-Elmer Inc. The ion is aimed at an angle of  $30^\circ$  from the vertical line of the substrate. The gun point is 13 cm from the vertical line of the substrate. The ion flowing density is  $25-45 \mu A/cm^2$ . The working pressure is  $8 \times 10^{-5}$  Torr at room temperature.

The second one is a neutral particle source made by Ion Tech of Britain. It is powered by cold cathode direct current. High energy ions generated by equal ion entity recombine and form atoms under the influence of electrostatic field near the output. In other words, it forms neutral particle beam. Such a particle source can avoid the damage on film crystal structure that is associated with electronic effect, it also can lower the bombardment efficiency caused by the electrons on the film surface. The

bombardment energy used in the experiment is 1.6-2.2 keV. The distance between the particle source and substrate varies from 6-10 cm for the purpose of adjusting the particle density of incoming particles. The particle beam has a 45° angle from the vertical line of substrate so as to ensure the even distribution of bombarding particles. The flowing density of the particles on the film is 10-20  $\mu\text{A}/\text{cm}^2$ . Since a cathode is used, the working pressure can be as high as  $5 \times 10^{-4}$  Torr.

/816

The third kind is Kaufman type, in which the ion energy is 200-750 eV. The ion source is about 19 cm from the substrate. The ion flowing density on the substrate is 30-100  $\mu\text{A}/\text{cm}^2$ . The substrate is lyophilized under  $5-9 \times 10^{-5}$  Torr.

Noteworthy, the first two are high energy bombardment, the third is low energy bombarding.

### III. OPTICAL PROPERTIES

If we measure the wavelength shift after cooling the filter, we can solve the phase change  $\alpha_{\phi H}$  and  $\alpha_{\phi L}$ , based on the heat expansion coefficient of ZnS(H) and MgF<sub>2</sub>(L). Their relation with temperature can be expressed as (11)

$$\alpha_{\phi H} = (1.99 \pm 0.11) \times 10^{-5} \text{ K}^{-1}, \alpha_{\phi L} = (0.91 \pm 0.06) \times 10^{-5} \text{ K}^{-1}.$$

In which K is absolute temperature. The peak value wavelength blue shift can be obtained given the temperature of substrates; vice versa.

On the other hand, the refractive index will change if the filter absorbs moisture from air. If ZnS has high packing density, we can focus on MgF<sub>2</sub> film. Change in refractive index or packing density is affected by many factors such as substrate temperature, evaporation rate and vacuum degree, etc. The primary

factor, substrate temperature is linked to the following equation (11):

$$\left( \frac{\delta N}{N} \right)_L = A_0 + A_1 \Delta \theta + A_2 (\Delta \theta)^2 (\%)$$

in which  $A_0=6.9$ ,  $A_1=-4.46 \times 10^{-2}$  and  $A_2=9.35 \times 10^{-5}$ ,  $\Delta \theta$  is the change in substrate temperature. With this we can calculate expected  $(\delta N/N)_L$  value and peak value wavelength red drift at different substrate temperature without bombarding, which can serve as contrast for the assisted case.

Three filters are used in the experiment. The first filter is bombarded at all layers; the second one is targeted at the inner surface and the layer which has low electronic field. The third filter is bombarded only at the low refractive index  $MgF_2$  layer. The data is shown in table 1. Fig.1 shows the relationship among  $(\delta N/N)_L$  and packing density  $P_L (=1-4.07 (\delta N/N)_L)$  and substrate temperature. Since deposition ratio ( $R$ ) and vacuum degree ( $P$ ) also affect these parameters, hence a characteristic factor  $Q$  is introduced. It defines a ratio of evaporating molecule to residual gas molecule.

\* The total losses (absorption+scattering) at peak wavelength.

$$Q = 10^{-3} R/P$$

Apparently,  $\delta N/N$  and  $P_L$  showed greater improvement despite the low values in fig.1.

If flowing density is increased, the wavelength drift can be reduced further. In film system  $A|M2LM|G, M=(HL)^2H$   $\lambda_0=530$  nm, using 1 keV,  $25 \mu\text{A}/\text{cm}^2$  and 1.5 keV,  $35 \mu\text{A}/\text{cm}^2$  and 2.0 keV,  $45 \mu\text{A}/\text{cm}^2$  ion beam for bombardment, the wavelength drift can be reduced to 2.6, 2.3 and 1.9 nm.

The filter discussed above is made by high energy ion assisted deposition. High energy ion bombardment invariably leads to higher losses. Usually, losses increase with the increase in ion energy, ion density and substrate temperature. Fig.2 is the measured absorption and scattering. Absorption of bombardment by 2 keV ions at  $\lambda = 633$  nm is 1 numerical scale higher than the conventional method. This is caused by the change of chemical nature of the materials used.

Table 2 Measured losses for  $G|(HL)^2H2LH(LH)^2|A$ ,  $\lambda_0=530$  nm

\* A polarizer with detuned spacers operates at 1.06  $\mu\text{m}$ . The results in table 3 refer to values of wavelength of 820 nm at normal incidence.

/819

The results of low energy bombardment are shown in table 3 and 4. Although, the optical adherence that is associated with low energy bombardment is not comparable to that of high energy bombardment, the losses can be reduced greatly.

Table 4 Measured losses of filters with low energy bombardment at  $\lambda=633 \text{ nm}$ 

design	absorption		scatter		bombarded parameter	
	conventional	ion-assisted	conventional	ion-assisted	eV	$\mu\text{A}/\text{cm}^2$
Air H2LF G $F=(HL)^2(LH)^2$	$3.6 \times 10^{-3}$	$4.2 \times 10^{-3}$	$4 \times 10^{-3}$	$7.4 \times 10^{-4}$	300	60
5-layer filter	$4.6 \times 10^{-4}$	$4.9 \times 10^{-4}$			400	65
Air  $A \frac{H}{2} B \frac{H}{2} A$  G $A=(\frac{H}{2} L \frac{H}{2})^2$ $B=(\frac{L}{2} H \frac{L}{2})^2$	$1.2 \times 10^{-3}$	$8.6 \times 10^{-3}$	$1 \times 10^{-2}$	$6.7 \times 10^{-3}$	200	40

We should point out that ZnS-MgF<sub>2</sub> multilayer film carries certain wavelength drift even after ion bombardment, and drift rate is three times faster than the filter made with conventional methods. This shows that ion bombardment can lead to shrinkage in space among column crystals.

#### IV. MECHANICAL PROPERTIES

In order to test the stress of the film formed by ion assisted bombarding, a stress testing device (19) similar to the one described by Heavens (19) was made. A steel ball with 0.125 mm radius was used to roll on the film to induce scratch, and scratch depth and width were determined by Talystep. Table 5 list data on high energy bombardment on ZnS and MgF<sub>2</sub> single layer films. According to Hertzian theory, glass substrate deforms and has a load under the steel ball, the contact radius of the steel ball is

$$a = \sqrt{\frac{Wg}{P\pi}} \text{ (cm)},$$

When, W=load (g), g=980 cms<sup>-2</sup>, P is the hardness of the glass scratch (=4x10<sup>10</sup> dan • cm<sup>2</sup>). The experimentally determined scratch width after bombarding the film in Table 5 is very close to the calculated value using this formula (68 μm). This demonstrated that the load is very close to the value of the deformed glass. In other words, the film bombarded by high energy ions is as hard as glass, and it has excellent adhesion.

Table 5 Scratch depths and widths determining by Talystep

layer	bombardment	load(g)	scratch depth (nm)	scratch width ( $\mu\text{m}$ )
ZnS	no	25	42 $\pm$ 7	4 $\pm$ 2
	yes	1500	1.5 $\pm$ 0.6	85 $\pm$ 5
$\text{MgF}_2$	no	10	12 $\pm$ 5	4.6 $\pm$ 2
	yes	1500	2 $\pm$ 1.2	80 $\pm$ 6

The stress of the film after low energy bombardment is lower than that of high energy bombardment. It has sizable improvement over the conventional method. Table 6 shows some of the experiment results.

The improvement in film stress is contingent upon its adhesion and hardness. However, the interacting force within  $\text{MgF}_2$  can also play an important role. Table 7 compiled measured parameters on ZnS,  $\text{MgF}_2$  and  $\text{Na}_3\text{AlF}_6$  using cat-eye interometer. Table 7 can shed more light on the reason why ion assisted ZnS- $\text{Na}_3\text{AlF}_6$  filter is more fragile than the one obtained thru conventional methods.

Table 6 Test results of the mechanical properties of films

## V. STRUCTURAL PROPERTIES AND ANTLASER DAMAGE CRITICAL VALUES

Examination on ZnS-MgF<sub>2</sub> single layer film and multilayer film by electron microscope has shown, ZnS film bombarded by high energy, high density ions tends to be nonstructural, while MgF<sub>2</sub> film tends to form columns. Analysis on the composition of ZnS and MgF<sub>2</sub> has shown that bombarded MgF<sub>2</sub> film is de-fluorinized. This ZnS film also has different composition in comparison to the conventional one.

Table 8 The results of laser damage

coating	laser damage(J/cm <sup>2</sup> )		bombarded parameter and later
	conventional	bombarded	
ZnS( $\frac{\lambda_0}{4}$ )	12.5	14.5	1keV 25 $\mu$ A/cm <sup>2</sup> HWFM 18ns
MgF <sub>2</sub> ( $\frac{\lambda_0}{4}$ )	15.4	24.8	
11-layer filter	5.4	4.0	
13-layer mirror	4.0	3.6	
ZnS( $\frac{\lambda_0}{4}$ )	9.1	11.2	300eV 45 $\mu$ A/cm <sup>2</sup> HWFM 10ns
MgF <sub>2</sub> ( $\frac{\lambda_0}{4}$ )	9.0	12.7	
9-layer filter	1.8	1.8	
21-layer polarizor	0.7	1.2	

Due to the change in optical property, mechanical property and structure, the laser damage critical values of the assisted film go up except for the middle layer film bombarded by high energy. Table 8 shows the result of laser damage, laser wavelength is  $1.06 \mu\text{m}$ .

## VI. CONCLUSIONS

Ion assisted deposition is not as effective as most oxides in promoting the optical stability of  $\text{ZnS}-\text{MgF}_2$  film regardless of the magnitude of bombardment. High energy bombardment is more effective in reducing wavelength drift and in improving packing density than low energy bombardment. But it can also lead to higher optical loss, therefore we can not expect it will improve the overall optical properties of the films. Since it can improve the stability of films, especially the possibility to make durable optical film with heat sensitive substrate, this makes it possible for expanded application of these materials. With this technology, we made  $\text{ZnS}-\text{MgF}_2$  multilayer films on Fabry-Perot set-up and at the end of optical fiber.
